Testing
Chapter 8.2
Syntactic Logic Coverage
Criteria
(Disjunctive Normal Form)

Paul Ammann & Jeff Offutt

http://www.cs.gmu.edu/~offutt/softwaretest/

Disjunctive Normal Form

- Common Representation for Boolean Functions
 - Slightly Different Notation for Operators
 - Slightly Different Terminology
- Basics:
 - A literal is a clause or the negation (overstrike) of a clause
 - Examples: a, a
 - A term is a set of <u>literals</u> connected by logical "and"
 - "and" is denoted by adjacency instead of ∧
 - Examples: ab, $a\overline{b}$, \overline{ab} for $a \wedge b$, $a \wedge \neg b$, $\neg a \wedge \neg b$
 - A (disjunctive normal form) predicate is a set of terms connected by "or"
 - "or" is denoted by + instead of ∨
 - Examples: $abc + \overline{ab} + a\overline{c}$
 - Terms are also called "implicants"
 - If a term is true, that implies the predicate is true

Implicant Coverage (8.2.1)

- Obvious coverage idea: Make each implicant evaluate to "true"
 - Problem: Only tests "true" cases for the predicate
 - Solution: Include DNF representations for negation

Implicant Coverage (IC): Given DNF representations of a predicate f and its negation f, for each implicant in f and f, TR contains the requirement that the implicant evaluate to true.

- Example: $f = ab + b\overline{c}$ $\overline{f} = \overline{b} + \overline{ac}$
 - Implicants: $\{ab, b\overline{c}, \overline{b}, \overline{ac}\}$
 - Possible test set: {TTF, FFT}
- Observation: IC is relatively weak

Improving on Implicant Coverage (8.2.2)

Additional Definitions:

- A proper subterm is a term with one or more clauses removed
 - Example: abc has 6 proper subterms: a, b, c, ab, ac, bc
- A prime implicant is an implicant such that no proper subterm of the implicant is also an implicant of the same predicate
 - Example: $f = ab + a\overline{b}c = ab\overline{c} + abc + a\overline{b}c = ab\overline{c} + ac$
 - Implicant ab is a prime implicant
 - Implicant $a\overline{b}c$ is not a prime implicant (due to proper subterm ac)
 - In a prime implicant, it is not possible to remove a term without changing the vale of the predicate
- A redundant implicant is an implicant that can be removed without changing the value of the predicate
 - Example: $f = ab + ac + b\overline{c}$
 - ab is redundant
 - Predicate can be written: $ac + b\overline{c}$

Unique True Points

- A minimal DNF representation is one with only prime, nonredundant implicants.
- A unique true point with respect to a given implicant is an assignment of truth values so that
 - the given implicant is true, and
 - all other implicants are false
- Hence a unique true point test focuses on just one implicant
- A minimal representation guarantees the existence of at least one unique true point for each implicant

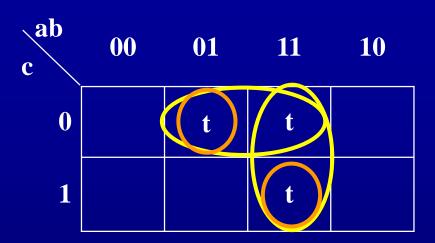

<u>Unique True Point Coverage (UTPC)</u>: Given minimal DNF representations of a predicate f and its negation f, TR contains a unique true point for each implicant in f and f.

Unique True Point Example

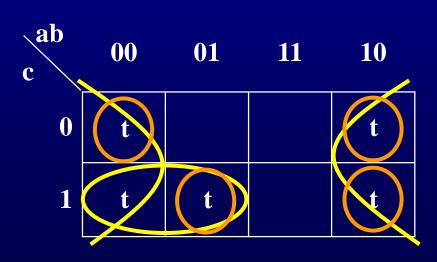

- Consider again: $f = ab + b\overline{c}$ $\overline{f} = \overline{b} + \overline{ac}$
 - Implicants: $\{ab, b\overline{c}, \overline{b}, \overline{ac}\}$
 - Each of these implicants is prime
 - None of these implicants is redundant
- Unique true points:
 - ab: {TTT}
 - *− bc*: {FTF}
 - <u>− b</u>: {FFF, TFF, TFT}
 - ac: {FTT}
- Note that there are three possible (minimal) tests satisfying UTPC
- UTPC is fairly powerful
 - Exponential in general, but reasonable cost for many common functions
 - No subsumption relation wrt any of the ACC or ICC Criteria
 - Can be proved with counter example (see textbook)

Unique True Point Example

- Unique true points:
 - − ab: {TTT}
 - − bc: {FTF}

Multiple Unique True Point Coverage (MUTP)

Multiple Unique True Point Coverage (MUTP): Given minimal DNF representations of a predicate f, for each implicant i, choose unique true points (UTPs) such that clauses not in i take on values T and F.

MUTP Example

- Consider again: $f = ab + b\overline{c}$ $\overline{f} = \overline{b} + \overline{ac}$
 - Implicants : $\{ab, b\overline{c}, \overline{b}, \overline{ac}\}$
 - Each of these implicants is prime
 - None of these implicants is redundant
- Unique true points:
 - ab: {TTT}
 - − bc: {FTF}
 - $-\overline{b}$: {FFF, TFF, TFT}
 - *− āc*: {FTT}
- Note: One possible (minimal) test set satisfying MUTP
 - For third clause (b), need first and third tests, but not second
 - To satisfy the MUTP, for implicant \overline{b} , choose UTPs such that clause a is \overline{T} and \overline{F} and clause c is \overline{T} and \overline{F} ;
 - Therefore, only {FFF, TFT} satisfies MUTP since FFT (vs TFF) is not a UTP for b
 - Note that MUTP is infeasible for the other three clauses (ab, $b\overline{c}$, $a\overline{c}$)
 - not enough UTPs for clauses not in implicant to take on all truth values

Near False Points (8.2.3)

- A near false point with respect to a <u>clause c</u> in implicant *i* is an assignment of <u>truth</u> values such that <u>f is false</u>, but if <u>c is negated</u> (and all other clauses left as is), <u>i (and hence f) evaluates to true</u>
- Relation to determination: at a near false point, c determines f
 - Hence we should expect relationship to ACC criteria

<u>Unique True Point and Near False Point Pair Coverage</u>
(<u>CUTPNFP</u>): Given a minimal DNF representation of a predicate f, for each clause c in each implicant i, TR contains a unique true point for i and a near false point for c such that the points <u>differ only in the truth value of c</u>.

- Note that definition only mentions f, and not f
- Clearly, CUTPNFP subsumes RACC

CUTPNFP Example

- Consider f = ab + cd
 - Implicant ab has 3 unique true points : {TTFF, TTFT, TTTF}
 - For clause a, we can pair unique true point $\underline{T}TFF$ with near false point $\underline{F}TFF$
 - For clause b, we can pair unique true point TTFF with near false point TFFF
 - Implicant cd has 3 unique true points : {FFTT, FTTT, TFTT}
 - For clause c, we can pair unique true point FFTT with near false point FFTT
 - For clause d, we can pair unique true point $FFT\underline{T}$ with near false point $FFT\underline{F}$
- CUTPNFP set: {TTFF, FFTT, TFFF, FTFF, FFTF}
 - First two tests are unique true points; others are near false points
- Rough number of tests required: # implicants * # literals

The MNFP and MUMCUT Criteria (8.2.3)

The next two criteria provide enough scaffolding to make guarantees about <u>fault detection</u> (see later slides)

Multiple Near False Point Coverage (MNFP): Given a minimal DNF representation of a predicate f, for each literal c in each implicant i, TR choose near false points (NFPs) such that clauses not in i take on values T and F.

MUMCUT: Given a minimal DNF representation of a predicate f, apply MUTP, CUTPNFP, and MNFP.

MUMCUT =
MUTP +
MNFP +
CUTPNFP

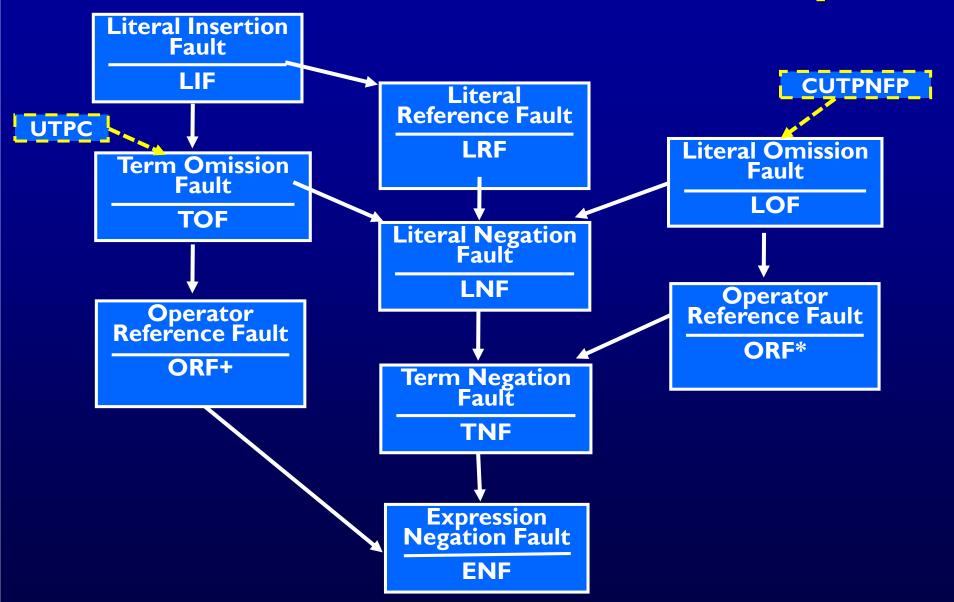

DNF Fault Classes

- ENF: Expression Negation Fault f = ab+c $f' = \overline{ab+c}$
- TNF: Term Negation Fault f = ab+c $f' = \overline{ab}+c$
- TOF: Term Omission Fault f = ab+c f' = ab
- LNF: Literal Negation Fault f = ab+c f' = ab+c
- LRF: Literal Reference Fault f = ab + bcd f' = ad + bcd
- LOF: Literal Omission Fault f = ab + c f' = a + c
- LIF: Literal Insertion Fault f = ab + c f' = ab + bc
- ORF+: Operator Reference Fault f = ab + c f' = abc
- ORF*: Operator Reference Fault f = ab + c f' = a + b + c

Key idea is that fault classes are related with respect to testing:

Test sets guaranteed to detect certain faults are also guaranteed to detect additional faults

Fault Detection Relationships

Understanding The Detection Relationships Consider the TOF (Term Omission Fault) class

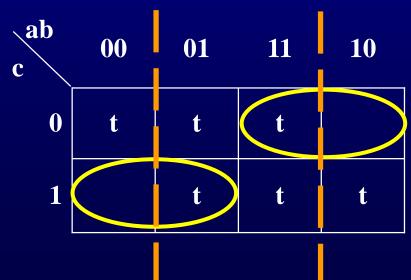

- - UTPC requires a unique true point for every implicant (term)
 - Hence UTPC detects all TOF faults
 - From the diagram, UTPC also detects:
 - All LNF faults (Unique true point for implicant now false)
 - All TNF faults (All true points for implicant are now false points)
 - All ORF+ faults (Unique true points for joined terms now false)
 - All ENF faults (Any single test detects this...)
- Although CUTPNFP does not subsume UTPC, CUTPNFP detects all fault classes that UTPC detects (Converse is false)
- Consider what this says about the notions of subsumption vs. fault detection
- Literature has many more powerful (and more expensive) DNF criteria
 - In particular, possible to detect entire fault hierarchy (MUMCUT an integration of all of the MUTP, MNFP and CUTPNFP strategies, where M is multiple)

Karnaugh Maps for Testing Logic Fair Warning Expressions (8.2.4)

- We use, rather than teach, Karnaugh Maps
- Newcomers to Karnaugh Maps probably need a tutorial
 - Suggestion: Google "Karnaugh Map Tutorial"
- Our goal: Apply Karnaugh Maps to concepts used to test logic expressions
 - Identify when a clause determines a predicate
 - Identify the negation of a predicate
 - Identify prime implicants and redundant implicants
 - Identify unique true points
 - Identify unique true point / near false point pairs
- No new material here on testing
 - Just fast shortcuts for concepts already presented

K-Map: A Clause Determines a Predicate

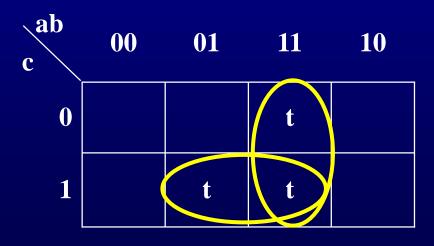

- Consider the predicate : $f = b + \bar{a}\bar{c} + ac$
- Suppose we want to identify when b determines f
- The dashed line highlights where b changes value
 - If two cells joined by the dashed line have different values for f, then b determines f for those two cells
 - -b determines f: $\overline{a}c + a\overline{c}$ (but NOT at ac or $\overline{a}\overline{c}$)
- Repeat for clauses a and c

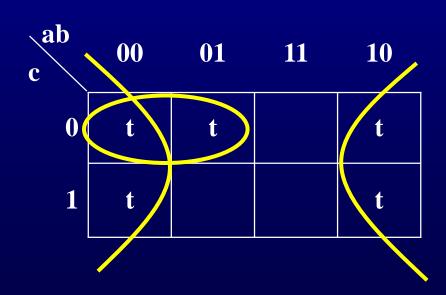

Introduction to Software Testing, Edition 2 (Ch 8)

K-Map: Negation of a predicate

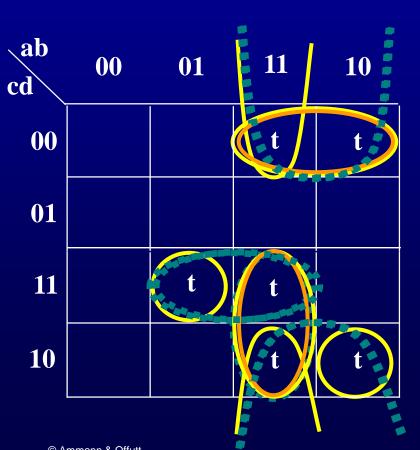

- Consider the predicate: f = ab + bc
- Draw the Karnaugh Map for the negation
 - Identify groups
 - Write down negation: $\overline{f} = \overline{b} + \overline{a} \overline{c}$

K-Map: Prime and Redundant Implicants

- Consider the predicate: $f = abc + abd + \overline{abcd} + \overline{abcd} + a\overline{cd}$
- Draw the Karnaugh Map
- Implicants that are not prime: abd, abcd, acd
- Redundant implicant: abd
- Prime implicants
 - Three: ad, bcd, abc
 - The last is redundant
 - Minimal DNF representation
 - $f = a\overline{d} + bcd$

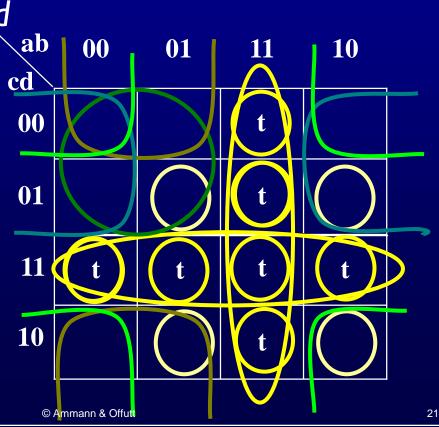

K-Map: Unique True Points

- Consider the predicate: f = ab + cd
- Three unique true points for ab
 - TTFF, TTFT, TTTF
 - TTTT is a (overlapping) true point, but not a unique true point
- Three unique true points for cd
 - FFTT, FTTT, TFTT
- Unique true points for \overline{f}

$$\overline{f} = \overline{a}\overline{c} + \overline{b}\overline{c} + \overline{a}\overline{d} + \overline{b}\overline{d}$$

- FTFT, TFFT, FTTF, TFTF

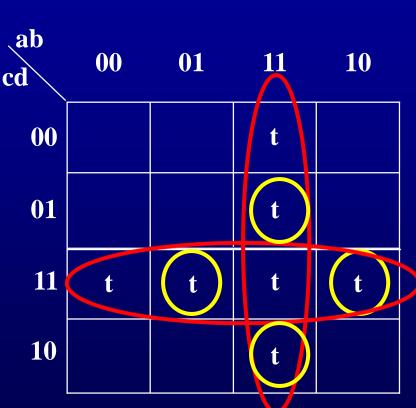

MUTP: Multiple Unique True Points

- For each implicant find unique true points (UTPs) so that
 - Literals not in implicant take on values T and F
- Consider the DNF predicate:

$$- f = ab + cd$$

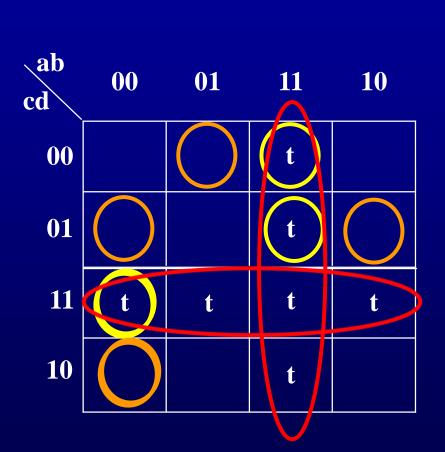

- For implicant ab
 - Choose TTFT, TTTF
- For implicant cd
 - Choose FTTT, TFTT
- MUTP test set
 - -{TTFT, TTTF, FTTT, TFTT}

CUTPNFP: Corresponding Unique True Point Near False Point Pairs

- Consider the DNF predicate: f = ab + cd
- For implicant ab
 - For a, choose UTP, NFP pairTTFF, FTFF
 - For b, choose UTP, NFP pair
 - TTFT, TFFT
- For implicant cd
 - For c, choose UTP, NFP pair
 - FFTT, FFFT
 - For d, choose UTP, NFP pair
 - FFTT, FFTF
- Possible CUTPNFP test set

Introduction to Software Testing, Edition 2 (Ch 8)

MNFP: Multiple Near False Points

- Find NFP tests for each literal such that all literals not in the term attain F and T
- Consider the DNF predicate:
 - f = ab + cd
- For implicant ab
 - Choose FTFT, FTTF for a
 - Choose TFFT, TFTF for b
- For implicant cd
 - Choose FTFT, TFFT for c
 - Choose FTTF, TFTF for d
- MNFP test set
 - {TFTF, TFFT, FTTF, FTFT}
- Example is small, but generally MNFP is large
